

## **This document describes the possible automation approach that can be applied.**

It has been split into two parts, however, both of them could be placed under the crontab scheduler. For more on crontab please refer to (<https://www.geeksforgeeks.org/crontab-in-linux-with-examples/>)

### **Scenario 1 (in the Orange VM)**

To upload a file that is present in the bucket of Minio to the Aidbox, consider the script [https://github.com/CODA-19/csv-to-fhir/blob/master/upload\\_minio\\_aidbox.py](https://github.com/CODA-19/csv-to-fhir/blob/master/upload_minio_aidbox.py), to explore more consider the approaches tried in jupyter [https://github.com/CODA-19/csv-to-fhir/blob/master/upload\\_minio\\_orange.ipynb](https://github.com/CODA-19/csv-to-fhir/blob/master/upload_minio_orange.ipynb)

To set authorization (this allows the Rest API to interact with the Aidbox), consider the description here [https://www.youtube.com/watch?v=xWtNNi\\_Q-dU&t=3s&ab\\_channel=HealthSamurai](https://www.youtube.com/watch?v=xWtNNi_Q-dU&t=3s&ab_channel=HealthSamurai)

Set the Client id and Client secret values (in the example script here, the first is set as `python_load_script`, and the later as `chum123`)

Consider the script ([https://github.com/CODA-19/csv-to-fhir/blob/master/upload\\_minio\\_aidbox.py](https://github.com/CODA-19/csv-to-fhir/blob/master/upload_minio_aidbox.py))

Assuming there is a bucket (container) by the name `chumtestbucket` which contains a file `culture_data.json.ndjson.gz`. In order to create the corresponding URL that would point to the specific file, call the method `create_presigned_url`. Once the URL is generated create the payload using the line `payload=({"source":url})`. Subsequently, access the Aidbox and perform the upload using the lines `requests.get()` and `requests.post()`

This completes the upload section using a python script

### **Scenario 2 (the different file generations)**

To achieve the task of file generation of different types, for instance csv, then encryption, and then json in a sequential manner, the help of crontab and shell scripts is considered. A typical crontab command scheduled for execution on a specific day/time (<https://www.geeksforgeeks.org/crontab-in-linux-with-examples/>) is given below (based on the way it is installed at our end)

Where `rxxyz` is the user name, `generate_csv.sh`, `generate_encrypted.sh`, and `generate_json.sh` are the shell scripts to generate csv, perform encryption, and the json files respectively.

```
15 19 * * SAT /usr/sbin/runuser -l rxxyz -c '/usr/local/sbin/generate_csv.sh' &&
'/usr/local/sbin/generate_encrypted.sh' && '/usr/local/sbin/generate_json.sh'
```

Each shell script would contain the line that executes the corresponding python code.
